Earning Capacity Hazard Data: Jan-2011 to Dec-2021

Markov Earning Capacity Hazards for Disability and Unemployment

Horner and Slesnick[1] provide the following definitions:

> *"Actual earnings are what a person actually earns, expected earnings are what a person is expected to earn, while earning capacity is what that person is able to earn."*

In order to be able to earn money, a person must have both the innate ability to work and have a job. In order to measure the probabilities of possessing innate ability and a job, John Ward Economics uses data from the Current Population Survey. In this document, we provide the data utilized from the Current Population Survey to measure earning capacity.

The Current Population Survey data are published by the U.S. Census Bureau and the Bureau of Labor Statistics.[2] The time period utilized for calculating the probability of unemployment or discouragement and probability of disability was January 2011 to December 2021.

By gender, education and age, we divided the U.S. population into groups. For the hazard of disability, inactive persons are those persons not-in-the-labor-force due to a disability that prevents work for at least the next six months or persons not-in-the-labor-force and reporting that they have a disability; and, active persons represent the balance of persons in the labor force and persons not-in-the-labor-force and without disability.

For the hazard of unemployment, inactive persons report that they are in the labor force and unemployed (official BLS 4-week definition) or persons not-in-the-labor force but wanting to work but feel that no job is available for them (BLS discouraged workers); and, active persons are the balance of the population. The risk probabilities of disability and unemployment are calculated using a Markov increment-decrement probability tracking movement between the inactive and active states.

Using the Current Population Survey public use microdata, we first find persons at one year apart in the survey and then record their activity at the two time periods. Because we are working with a sub-sample of matched persons found in the Current Population Survey, we re-weight the matched sample to the entire sample so that the proportion of matched persons equals that of all persons by gender, race, age, and activity.

We then find the number of persons remaining inactive-to-inactive at one year apart intervals and those inactive-to-active, active-to-inactive, and active-to-active. We smooth the proportion of the population in each state by age using localized regression.

Attached you will find a data table of the transition probabilities of moving from one state to another, age-to-age. We also provide charts of that data smoothed and unsmoothed.
